Stochastic Calculus for Finance I: The Binomial Asset Pricing Model by Steven E. Shreve

Chapter 6 Interest-Rate-Dependent Assets

Answers by Aaron Fu

21 April, 2019

Please refer to the book for the exercises themselves. The text in front of each answer serves only as a summary of the question.

Please refer to the table below for the notation conversion. Changes are made to make symbols more compact, and to make the forward measure more distinguishable from the risk-neutral one.

Book	Answers	Note
$B_{n,m}$	B_n^m	time- n price of a bond that matures at time m
$\Delta_{n,m}$	Δ_n^m	number of m -maturity zero-coupon bonds held by the agent between time n and $n + 1$
$\tilde{\mathbb{P}}^m$	$\hat{\mathbb{P}}^m$	probability under the m -forward measure
$\tilde{\mathbb{E}}_n^m$	$\hat{\mathbb{E}}_n^m$	time- n conditional expectation under the m -forward measure

Exercise 6.2 Verify that the discounted value of the static hedging portfolio for a forward is a martingale under $\tilde{\mathbb{P}}$.

Answer: To hedge a short position in a forward contract that is initiated at time n with delivery date m , the agent should, at time n , long 1 share of stock and short S_n/B_n^m unit of m -maturity zero-coupon bond. This constructs a static hedging portfolio. The time- n value of the hedging portfolio is

$$X_n = S_n - \left(\frac{S_n}{B_n^m} \right) B_n^m (= 0)$$

To show its discounted value is $\tilde{\mathbb{P}}$ -martingale, note that

$$\begin{aligned} \tilde{\mathbb{E}}_n(D_{n+1} X_{n+1}) &= \tilde{\mathbb{E}}_n \left[D_{n+1} \left(S_{n+1} - \left(\frac{S_n}{B_n^m} \right) B_{n+1}^m \right) \right] \\ &= \tilde{\mathbb{E}}_n(D_{n+1} S_{n+1}) - \left(\frac{S_n}{B_n^m} \right) \tilde{\mathbb{E}}_n(D_{n+1} B_{n+1}^m) \quad \dots \text{linearity} \\ &= D_n S_n - \left(\frac{S_n}{B_n^m} \right) D_n B_n^m \quad \dots \text{discounted stock, bond prices are } \tilde{\mathbb{P}}\text{-martingale} \\ &= D_n X_n \end{aligned}$$

Note: that discounted bond prices are $\tilde{\mathbb{P}}$ -martingale can be shown by, for $0 \leq k \leq n \leq m$,

$$\tilde{\mathbb{E}}_k(D_n B_n^m) = \tilde{\mathbb{E}}_k \left[D_n \tilde{\mathbb{E}}_n \left(\frac{D_m}{D_n} \right) \right] = \tilde{\mathbb{E}}_k[\tilde{\mathbb{E}}_n(D_m)] = \tilde{\mathbb{E}}_k(D_m) = \tilde{\mathbb{E}}_k \left(D_k \cdot \frac{D_m}{D_k} \right) = D_k \tilde{\mathbb{E}}_k \left(\frac{D_m}{D_k} \right) = D_k B_k^m$$

Exercise 6.3 Use properties of conditional expectations to show that

$$\frac{1}{D_n} \tilde{\mathbb{E}}_n[D_{m+1} R_m] = B_n^m - B_n^{m+1}$$

Answer: Note that $(1 + R_m) = \frac{D_m}{D_{m+1}} \implies R_m = \frac{D_m}{D_{m+1}} - 1$. We have

$$\begin{aligned} \frac{1}{D_n} \tilde{\mathbb{E}}_n[D_{m+1} R_m] &= \frac{1}{D_n} \tilde{\mathbb{E}}_n \left[D_{m+1} \left(\frac{D_m}{D_{m+1}} - 1 \right) \right] \\ &= \frac{1}{D_n} \tilde{\mathbb{E}}_n [D_m - D_{m+1}] \\ &= \tilde{\mathbb{E}}_n \left[\frac{D_m}{D_n} \right] - \tilde{\mathbb{E}}_n \left[\frac{D_{m+1}}{D_n} \right] && \dots \text{take in what is known, linearity} \\ &= B_n^m - B_n^{m+1} && \dots \text{definition} \end{aligned}$$

Remark: What's the difference between

- (a) the time- n contract price to pay R_m at time $m + 1$ (see *page 155*), and
- (b) the time- n forward price to deliver R_m at time $m + 1$ (see *page 156*)?

Expressed in formula, the former is $B_n^{m+1} F_n^m = B_n^m - B_n^{m+1}$ while the latter is just F_n^m .

But the fundamental difference is that the former is the price to pay at time n , while the latter, as any other strike price of a forward contract, is the price to pay at time $m + 1$.

An example with concrete numbers.

Say $n = 3$, $m = 7$. At time $n = 3$, let's say $B_n^m = B_3^7 = \$0.93$ and $B_n^{m+1} = B_3^8 = \$0.87$.

It can be calculated that the time- n forward interest rate for the period between times m and $m + 1$ is

$$F_n^m = \frac{B_n^m}{B_n^{m+1}} - 1 = \frac{\$0.93}{\$0.87} - 1 = 6.90\%$$

At time $n = 3$, we do not know $R_m = R_7$ which is not unveiled until time $m = 7$.

However, we may, at time $n = 3$, sign a contract that promises to pay $R_m = R_7$ at time $m + 1 = 8$.

For this contract we charge a no-arbitrage price at $B_n^{m+1} F_n^m = \$0.87 \times 6.90\% = \0.06 , which the counterparty must pay immediately at time $n = 3$, for the entitlement to receive R_7 at time $m + 1 = 8$. This amount can also be worked out by $B_n^m - B_n^{m+1} = \$0.93 - \$0.87 = \$0.06$.

As another case, we may short a forward contract, which promises to deliver $R_m = R_7$ at time $m + 1 = 8$. Our counterparty, who long the forward contract, is required to pay a strike price fixed at $F_n^m = \$0.069$ at time $m + 1 = 8$ in exchange for the delivery of $R_m = R_7$.

Exercise 6.4 Using data provided in the book, construct a hedge for a short position in a caplet paying $(R_2 - \frac{1}{3})^+$ at time three. In particular,

(i) Determine $V_1(H)$ and $V_1(T)$.

(ii) Show how to begin with $\frac{2}{21}$ at time zero and invest in the money market and maturity-two bond in order to have a portfolio X_1 at time one that agrees with V_1 . Why do we invest in the maturity-two bond rather than the maturity-three bond?

(iii) Show how to take the portfolio value X_1 at time one to a portfolio value X_2 at time two that agrees with V_2 . Why do we at this step invest in the maturity-three bond rather than the maturity-two bond?

Answer: (i) According to the risk-neutral pricing formula, $D_1 V_1 = \tilde{\mathbb{E}}_1(D_2 V_2)$, or $V_1 = \tilde{\mathbb{E}}_1(\frac{D_2}{D_1} V_2) = \tilde{\mathbb{E}}_1(\frac{1}{1+R_1} V_2)$. In particular,

$$V_1(H) = \frac{1}{1 + R_1(H)} \left[\tilde{\mathbb{P}}\{\omega_2 = H \mid \omega_1 = H\} \cdot V_2(HH) + \tilde{\mathbb{P}}\{\omega_2 = T \mid \omega_1 = H\} \cdot V_2(HT) \right] = \frac{1}{1 + \frac{1}{6}} \cdot \left(\frac{2}{3} \cdot \$\frac{1}{3} + \frac{1}{3} \cdot \$0 \right) = \$\frac{4}{21}$$

$$V_1(T) = \frac{1}{1 + R_1(T)} \left[\tilde{\mathbb{P}}\{\omega_2 = H \mid \omega_1 = T\} \cdot V_2(TH) + \tilde{\mathbb{P}}\{\omega_2 = T \mid \omega_1 = T\} \cdot V_2(TT) \right] = \frac{1}{1 + \frac{2}{5}} \cdot \left(\frac{1}{2} \cdot \$0 + \frac{1}{2} \cdot \$0 \right) = \$0$$

(ii) The number of maturity-two zero-coupon bonds to hold between times zero and one is

$$\Delta_0^2 = \frac{V_1(H) - V_1(T)}{B_1^2(H) - B_1^2(T)} = \frac{\frac{4}{21} - 0}{\frac{6}{7} - \frac{5}{7}} = \frac{4}{3}$$

Since we have sold the caplet for $X_0 = V_0 = \$\frac{2}{21}$, the money-market account position is

$$X_0 - \Delta_0^2 B_0^2 = \$\frac{2}{21} - \frac{4}{3} \cdot \$\frac{11}{14} = -\$ \frac{20}{21}$$

The negative number indicates we should borrow $\$ \frac{20}{21}$ from the money market.

If the first coin toss is H , then at time one, the hedging portfolio has value

$$X_1(H) = \Delta_0^2 B_1^2(H) + (1 + R_0)(X_0 - \Delta_0^2 B_0^2) = \frac{4}{3} \cdot \$\frac{6}{7} - (1 + 0) \cdot (-\$ \frac{20}{21}) = \$\frac{4}{21}$$

If the first coin toss is V , then at time one, the hedging portfolio has value

$$X_1(T) = \Delta_0^2 B_1^2(T) + (1 + R_0)(X_0 - \Delta_0^2 B_0^2) = \frac{4}{3} \cdot \$\frac{5}{7} - (1 + 0) \cdot (-\$ \frac{20}{21}) = \$0$$

Note that the hedging portfolio has a time-one value X_1 that agrees with V_1 , regardless of the coin-toss result.

- Why do we invest in the maturity-two bond?

Because at time zero, we want to hedge against the stochastic interest rate R_1 which is unveiled at time one, which is incorporated in the price of the maturity-two bond. In fact, the price of the maturity-two bond is fully determined by two interest rates: R_0 , which is known at time zero, and R_1 , which we want to hedge against.

- Why do we not invest in the maturity-three bond?

The price of the maturity-three bond additionally depends on R_2 , which we shouldn't worry about at time zero. Moreover, in this case, $B_1^3(H) = B_1^3(T) = \frac{4}{7}$, which means it has no randomness between times zero and one, and thus cannot be used as a hedge. A binomial model requires $0 < d < 1 + r < u$, and this violates the assumption as $d = u$.

(iii) If the first coin toss is H , the number of maturity-three zero-coupon bonds to hold between times one and two is

$$\Delta_1^3(H) = \frac{V_2(HH) - V_2(HT)}{B_2^3(HH) - B_2^3(HT)} = \frac{\frac{1}{3} - 0}{\frac{1}{2} - 1} = -\frac{2}{3}$$

The negative number indicates that we should short $-\frac{2}{3}$ unit of the maturity-three bond. The cash generated will be invested in the money market.

With hedging portfolio value $X_1(H) = \$\frac{4}{21}$, the money market position is

$$X_1(H) - \Delta_1^3(H) B_1^3(H) = \$\frac{4}{21} - (-\frac{2}{3}) \cdot \$\frac{4}{7} = \$\frac{4}{7}$$

If the first two coin tosses are HH , the hedging portfolio has value

$$X_2(HH) = \Delta_1^3(H)B_2^3(HH) + [1 + R_1(H)][X_1(H) - \Delta_1^3(H)B_1^3(H)] = \left(-\frac{2}{3}\right) \cdot \$\frac{1}{2} + \left(1 + \frac{1}{6}\right) \cdot \$\frac{4}{7} = \$\frac{1}{3}$$

If the first two coin tosses are HT , the hedging portfolio has value

$$X_2(HT) = \Delta_1^3(H)B_2^3(HT) + [1 + R_1(H)][X_1(H) - \Delta_1^3(H)B_1^3(H)] = \left(-\frac{2}{3}\right) \cdot \$1 + \left(1 + \frac{1}{6}\right) \cdot \$\frac{4}{7} = \$0$$

If, however, the first coin toss is T , the hedging strategy is trivial. We start with $X_1(T) = \$0$ and do nothing, as $V_2(TH) = V_2(TT) = \$0$.

We have shown that the hedging portfolio has time-two value X_2 that agrees with V_2 . That is, $X_2(HH) = V_2(HH) = \$\frac{1}{3}$, and they are both zero in all other cases.

It is by the same token that we invest in the maturity-three bond rather than the maturity-two bond at this step, since the randomness of R_2 , which we want to hedge against, is not incorporated in the price of the latter.

Exercise 6.5 (i) Use (6.4.8) and (6.2.5) to show that $F_n^m, n = 0, 1, \dots, m$ is a martingale under the $(m+1)$ -forward measure $\widehat{\mathbb{P}}^{m+1}$.

(ii) Compute $F_0^2, F_1^2(H)$, and $F_1^2(H)$ in the *Ho-Lee model* example in the book and verify the martingale property $\widehat{\mathbb{E}}^3[F_1^2] = F_0^2$.

Answer: (i) For $0 \leq k \leq n \leq m$,

$$\begin{aligned} \widehat{\mathbb{E}}_k^{m+1}(F_n^m) &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k(D_{m+1} F_n^m) && \dots (6.4.8) \\ &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k \left[D_{m+1} \frac{B_n^m - B_n^{m+1}}{B_n^{m+1}} \right] && \dots \text{definition} \\ &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k \left[D_{m+1} \frac{B_n^m - B_n^{m+1}}{\frac{1}{D_n} \widetilde{\mathbb{E}}_n(D_{m+1})} \right] && \dots \text{definition, take out what is known} \\ &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k \left[\widetilde{\mathbb{E}}_n \left[\frac{D_{m+1}(D_n B_n^m - D_n B_n^{m+1})}{\widetilde{\mathbb{E}}_n(D_{m+1})} \right] \right] && \dots \text{iterated conditioning} \\ &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k \left[(D_n B_n^m - D_n B_n^{m+1}) \frac{\widetilde{\mathbb{E}}_n(D_{m+1})}{\widetilde{\mathbb{E}}_n(D_{m+1})} \right] && \dots \text{take out what is known} \\ &= \frac{1}{D_k B_k^{m+1}} \widetilde{\mathbb{E}}_k(D_n B_n^m - D_n B_n^{m+1}) && \dots \text{cancelling} \\ &= \frac{D_k B_k^m - D_k B_k^{m+1}}{D_k B_k^{m+1}} && \dots (6.2.5) \\ &= \frac{B_k^m - B_k^{m+1}}{B_k^{m+1}} && \dots \text{cancelling} \\ &= F_k^m && \dots \text{definition} \end{aligned}$$

(ii) Using the numbers in the book, we have

$$F_0^2 = \frac{B_0^2 - B_0^3}{B_0^3} = \frac{0.9071 - 0.8639}{0.8639} = 5.0\%$$

$$F_1^2(H) = \frac{B_1^2(H) - B_1^3(H)}{B_1^3(H)} = \frac{0.9479 - 0.8955}{0.8985} = 5.5\%$$

$$F_1^2(T) = \frac{B_1^2(T) - B_1^3(T)}{B_1^3(T)} = \frac{0.9569 - 0.9158}{0.9158} = 4.5\%$$

$$\begin{aligned}\hat{\mathbb{E}}^3(F_1^2) &= \sum_{\omega_1=H} \hat{\mathbb{P}}^3(\omega_1\omega_2\omega_3)F_1^2(H) + \sum_{\omega_1=H} \hat{\mathbb{P}}^3(\omega_1\omega_2\omega_3)F_1^2(T) \\ &= (0.1232 + 0.1232 + 0.1244 + 0.1244) \cdot 5.5\% + (0.1256 + 0.1256 + 0.1268 + 0.1268) \cdot 4.5\% \\ &= 5.0\%\end{aligned}$$
